Practical: Deploy WordPress using Docker Compose

Step 1: Create a Project Directory

First, I created a folder for the WordPress Docker project.

```
mkdir wordpress_docker  
cd wordpress_docker
```

Step 2: Create Docker Compose File

I created a Docker Compose configuration file.

```
notepad docker-compose.yml
```

Step 3: Define WordPress and MySQL Services

Inside the docker-compose.yml file, I defined two services:

- WordPress container
- MySQL database container

I also configured:

- database credentials
- container names
- ports
- persistent storage using volumes.

Step 4: Save the Docker Compose File

I saved the file as:

```
docker-compose.yml
```

in the project directory.

Step 5: Start the Containers

I ran the following command to start the containers in detached mode.

```
docker compose up -d
```

Step 6: Verify Running Containers

I verified that the containers were running using the command:

Step 7: Access WordPress in Browser

I opened the web browser and accessed WordPress using:

```
http://localhost:8082
```

The WordPress installation page appeared.

Step 8: Complete WordPress Installation

I entered the required details:

- Site Title
- Admin Username
- Password
- Email Address

Then I clicked Install WordPress.

Step 9: Login to WordPress Dashboard

After installation, I logged in using the admin credentials and accessed the WordPress dashboard to manage the website.
